ABSTRACT—A field survey of macrofungi from the Hindu Kush range of District Swat revealed a fungus morphologically similar to *Leucoagaricus* but representing a new species, here named *L. brunneus*. A detailed description and comparison with closely allied taxa are provided. Maximum likelihood analysis based on the internal transcribed spacer rDNA region (ITS) confirm its placement in *Leucoagaricus* sect. *Rubrotincti*.

KEY WORDS—Agaricaceae, Agaricales, Agaricomycetes, phylogeny, polyphyletic

Introduction

Leucoagaricus Locq. ex Singer, assigned to the family Agaricaceae (Singer 1986, Vellinga 2004), is represented by over 100 species in the northern and southern hemispheres (Kumar & Manimohan 2009; Ge 2010; Liang & al. 2010; Vellinga 2010; Vellinga & Balsley 2010; Vellinga & al. 2010; Muñoz & al. 2012, 2014; Kumari & Atri 2013; Malysheva & al. 2013; Ye & al. 2014; Ge & al. 2015; Qasim & al. 2015; Dovana & al. 2017; Hussain & al. 2018; Usman & Khalid 2018). From Pakistan only ten *Leucoagaricus* species have been reported previously: *L. asiaticus* Qasim & al., *L. badius* S. Hussain & al., *L. lahorensiformis* S. Hussain

& al., *L. lahorensis* Qasim & al., *L. leucothites* (Vittad.) Wasser, *L. pabbiensis* Usman & Khalid, *L. pakistaniensis* Jabeen & Khalid, *L. serenus* (Fr.) Bon & Boiffard, *L. sultanii* S. Hussain & al., and *L. umbonatus* S. Hussain & al. (Ahmad & al. 1997, Ge & al. 2015, Qasim & al. 2015, Hussain & al. 2018, Usman & Khalid 2018). The genus is characterized morphologically by small- to medium-sized basidiomata with entire pileus margins, free lamellae, a central, equal to bulbous stipe, a membranous, persistent annulus, a white, cream, or pink spore print white, usually dextrinoid basidiospores, the presence of cheilocystidia, rare occurrence of pleurocystidia, and absence of clamp connections (Singer 1986).

Several molecular phylogenies indicate that *Leucoagaricus* is polyphyletic (Johnson & Vilgalys 1998, Johnson 1999, Vellinga 2004). Vellinga (2003, 2004) showed that *Leucoagaricus* and *Leucocoprinus* species cluster together phylogenetically but intermix within a single clade. Because of the large number of species in the clade and relatively limited molecular data, the taxonomic and phylogenetic relationships among many *Leucoagaricus* and *Leucocoprinus* species have not yet been resolved.

During the present investigation, one *Leucoagaricus* specimen collected from the Shawar Valley (district Swat, Khyber Pakhtunkhwa, Pakistan) is proposed here as a new species, *L. brunneus*, supported by our morphological and phylogenetic analyses.

Material & methods

The mushroom was collected during a forest foray in Shawar valley, Khyber Pakhtunkhwa, Pakistan, during the 2017 monsoon season and photographed at the sampling site. Macrocharacters were recorded from the fresh basidioma, with colors coded according to Munsell's Soil Color Charts (1975). The specimen was air dried for further analyses and deposited in the Herbarium of University of the Punjab, Quaid-e-Azam Campus, Lahore, Pakistan (LAH).

For microscopic studies, fruiting body tissues were mounted in 2% KOH and Congo red (to increase contrast). Basidia, basidiospores, cheilocystidia, and pellicular elements were measured using ScopeImage 9.0. DNA extraction followed Bruns (1995). The internal transcribed spacer region (ITS1–5.8S–ITS2 = ITS) was amplified with the ITS1F/ITS4 primer combination (White & al. 1990, Gardes & Bruns 1993). PCR products were purified and both strands were sequenced by Beijing Genomic Institute (BGI).

For phylogenetic analysis, an ITS consensus sequence was generated in BioEdit (Hall 1999) and BLAST searched at NCBI (<https://www.ncbi.nlm.nih.gov/>); closely related sequences in *L. sect. Rubrotincti* were retrieved from both database and literature (Hussain & al. 2018). *Lepiota subgracilis* Kühner was chosen as outgroup (Liang & al. 2010). All sequences were aligned online using PRANK tool

(<https://www.ebi.ac.uk/goldman-srv/webprank/>). Gaps were treated as missing data. The final aligned ITS dataset was phylogenetically analyzed through MEGA 6.0 software. Maximum Likelihood (ML) analysis was performed by selecting Kimura 2-parameter with Gamma Distributed model using Best-Fit Substitution Model approach in MEGA 6.0 (Tamura & al. 2013).

Taxonomy

Leucoagaricus brunneus Z. Ullah, Jabeen & Khalid, sp. nov.

FIGS 1, 2

MB 827985

Differs from *Leucoagaricus truncatus* by its smaller size, smooth shiny non-squamulose pileus with brown striations, and its longer and narrower elongate to cylindrical basidiospores.

TYPE: Pakistan. Khyber Pakhtunkhwa Province, Swat district, Lower Shawar, under *Quercus oblongata* D. Don (*Fagaceae*), 8 July 2017, Zia Ullah LS4 (Holotype, LAH35862; GenBank MH990662).

ETYMOLOGY: *brunneus* (Latin) refers to the brown coloration of the pileus fibrils.

FIGURE. 1. *Leucoagaricus brunneus* (holotype, LAH35862). Basidioma. Scale bars = 0.5 cm.

FIGURE 2. *Leucoagaricus brunneus* (holotype, LAH35862). A. Basidiospores; B. Basidia; C. Cheilocystidia; D. Pileipellis; E. Stipitipellis. Scale bars = 10 μ m. (Drawing by Sana Jabeen.)

PILEUS 35 mm diam, plane with incurved margins and umbonate center, surface smooth and shiny, dark brown (10YR1/2) from center to lighter brown (10YR2/4) towards margin in the form of radial striations, context cream.

LAMELLAE free, close to crowded, margins entire, cream. LAMELLULAE absent. STIPE central, $9 \times 4\text{--}8$ mm, narrower towards the apex and wider (≤ 8 mm) towards the base, then again narrowing (≤ 6 mm) at the base, cream with grayish brown (10YR4/4) patches over the central part; annulus superior (at the center of the upper half), white.

BASIDIOSPORES [30/1/1] $(8.0\text{--})8.2\text{--}10.5(\text{--}10.6) \times (4\text{--})4.1\text{--}4.9(\text{--}5.1)$ μm , $Q = (1.8\text{--})1.9\text{--}2.1(\text{--}2.2)$, $avQ = 2$, elongate to cylindrical in face view, amygdaliform in side view, smooth, germ pore lacking, dextrinoid in Melzer's reagent, hyaline in KOH. BASIDIA $17.3\text{--}19 \times 7.4\text{--}8.1$ μm , clavate, smooth, hyaline, 4-spored. CHEILOCYSTIDIA $29.7\text{--}32.8 \times 8.5\text{--}12.7$ μm , clavate to subclavate, hyaline, without crystals. PLEUROCYSTIDIA absent. PILEIPELLIS a cutis with slightly clavate to cylindrical elements, $4.1\text{--}6.7$ μm diam, hyaline in KOH. STIPITPELLIS cylindric hyphae, $3.0\text{--}5.2$ μm diam, hyaline in KOH. CLAMP CONNECTIONS absent in all tissues.

ECOLOGY & DISTRIBUTION—Saprobic and solitary on humus-rich soil under *Quercus oblongata* [= *Q. incana* Roxb., nom. illeg.], at 1200 m elevation, in moist temperate *Quercus* vegetation.

Phylogenetic analysis

The 72 ITS sequence dataset (TABLE 1, FIG. 3) comprises 757 positions. Maximum likelihood analysis clusters the local collection in a sister clade with *L. truncatus* Z.W. Ge & Zhu L. Yang and *L. purpureolilacinus* Huijsman with a bootstrap support of 72% (FIG. 3).

Discussion

Leucoagaricus brunneus can be distinguished from *L. truncatus* based on basidioma size. *Leucoagaricus truncatus* produces medium to large (40–80 mm) basidiomata (Ge & al. 2015) and is further separated by the orange-white to gray-orange furfuraceous squamules (Ge & al. 2015) on its pileus surface in contrast to the smooth shiny pileus with brown striations that distinguish *L. brunneus*. *Leucoagaricus truncatus* is further separated microscopically by its more broadly ovoid and broadly amygdaliform basidiospores (Ge & al. 2015). The ITS sequence analysis also provides strong bootstrap support for *L. brunneus* as an independent taxon.

Leucoagaricus brunneus differs from *L. purpureolilacinus*, which is characterized by a pinkish brown pileus and presence of crystalliferous cheilocystidia (Vellinga 2001).

Pileus morphology also separates *Leucoagaricus brunneus* with its dark brown umbo and brownish striations running towards the margin from

the center from *L. serenus* and *L. crystallifer* Vellinga, both characterized by whitish basidiomata and pilei with white-to cream obtuse umbos with obvious striations near the margins. *Leucoagaricus serenus* and *L. crystallifer* are further distinguished by their ovoid and broadly amygdaliform

TABLE 1. *Leucoagaricus* species and specimens, and *Lepiota subgracilis* outgroup, used for ITS phylogenetic analyses.

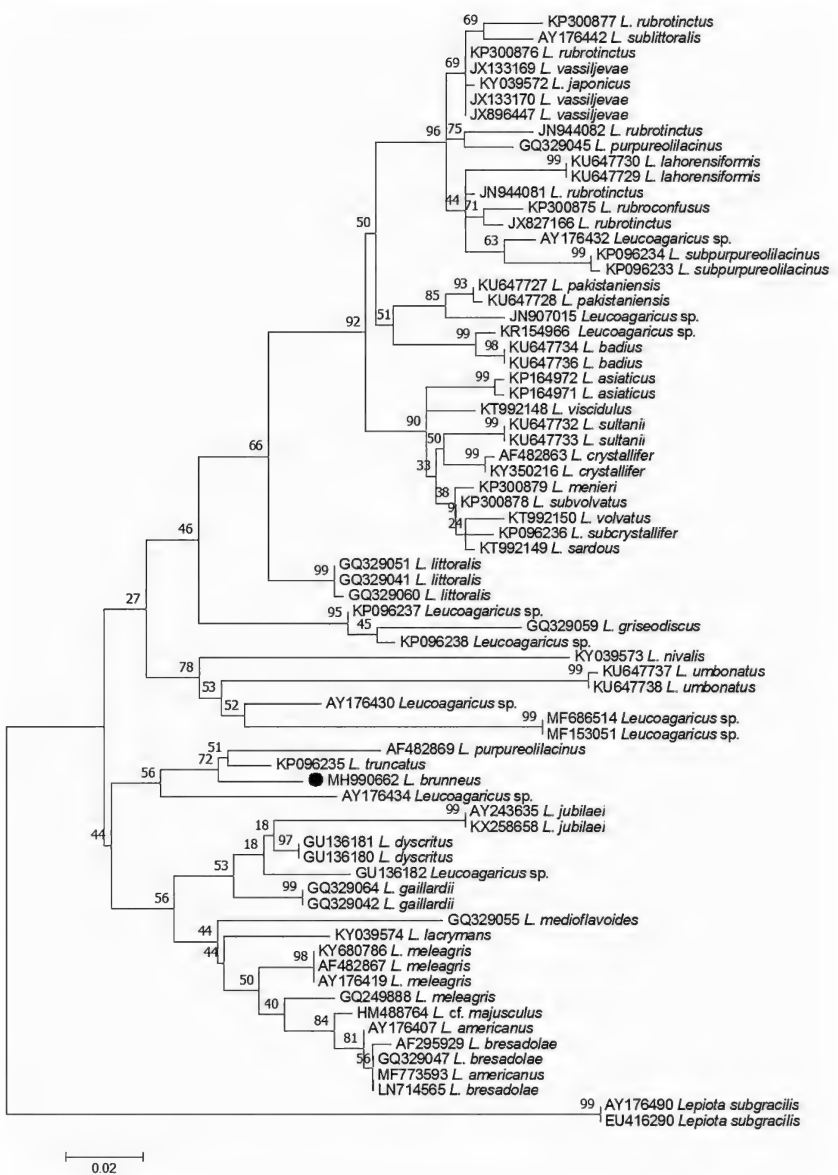

FIGURE 3. Molecular phylogenetic analysis of ITS sequences of *Leucoagaricus* species, with *Lepiota subgracilis* outgroup. The evolutionary history was inferred by using the Maximum Likelihood method based on the Tamura 3-parameter model. The analysis involved 72 nucleotide sequences. All positions containing gaps and missing data were eliminated. There were a total of 448 positions in the final dataset. Our new species is marked with ●.

basidiospores, contrasting with the elongated to cylindric and amygdaliform basidiospores of *L. brunneus*. In addition, in *L. crystallifer* the cheilocystidia have obvious crystals on the surface (Vellinga 2000, 2001) unlike the smooth cheilocystidia of *L. brunneus*.

In comparison with Pakistani *Leucoagaricus* species, *L. brunneus* differs from *L. asiaticus* characterized by oblong to ellipsoid spores and cheilocystidia with crystals at the apex (Ge & al. 2015). Morphologically, its pileus color distinguishes *L. brunneus* (brown) from *L. badius* (red), *L. pakistaniensis* (whitish), *L. lahorensis* (dark reddish brown), *L. lahorensiformis* (light orange), *L. umbonatus* (yellowish pink), and *L. sultanii* (dark yellow) (Qasim & al. 2015, Hussain & al. 2018). Basidiospore morphology also separates these species from *L. brunneus* (Qasim & al. 2015, Hussain & al. 2018). All the earlier named Pakistani species have smaller spores except *L. lahorensis*, whose spores measure more or less the same as *L. brunneus* (Qasim & al. 2015), and none except *L. brunneus* present the same basidiospore shape—elongate to cylindrical in face view and amygdaliform in profile: amygdaliform to oblong in *L. badius* ($6.5\text{--}7.5 \times 4\text{--}5\text{ }\mu\text{m}$), ellipsoid to rarely amygdaliform in *L. pakistaniensis* ($7.5\text{--}8 \times 4.5\text{--}5\text{ }\mu\text{m}$), broadly ellipsoid to ellipsoid in *L. lahorensis* ($8\text{--}10.6 \times 6.4\text{--}7.6\text{ }\mu\text{m}$), fusiform to amygdaliform in *L. lahorensiformis* ($6.5\text{--}7.5 \times 3.5\text{--}4\text{ }\mu\text{m}$), amygdaliform to ellipsoid in *L. umbonatus* ($5.5\text{--}6.5 \times 3.5\text{--}4\text{ }\mu\text{m}$), and amygdaliform to ellipsoid in *L. sultanii* ($5.5\text{--}7 \times 3.5\text{--}4.5\text{ }\mu\text{m}$) (Qasim & al. 2015, Hussain & al. 2018). The crystals on the cheilocystidial apices in *L. lahorensiformis* and *L. sultanii* also separate both species from *L. brunneus*.

Therefore a combination of morphological differences and a phylogenetic bootstrap support of 72% (FIG. 3) provide convincing support for our new species, *Leucoagaricus brunneus*.

Acknowledgments

The work is funded by HEC Research Project number 20-3383/HEC/R&D/14/184. Sincere thanks to Dr. Chang-Lin Zhao (Forestry College, Southwest Forestry University, Yunnan, P.R. China) and Dr. Shah Hussain (Center for Plant Sciences and Biodiversity, University of Swat, Pakistan) for presubmission review of the manuscript. Their comments and suggestions greatly helped to improve the document. We are thankful to Sheraz Khan, Numan Fazal, and Niaz Ali for their help in sampling.
